

# Quality monitoring and bias correction for satellite data in JRA-25

Shinya Kobayashi  
Japan Meteorological Agency

# Table of Contents

- Outlines of JRA-25
- Precise quality monitoring for TOVS data
- Assimilating schemes for TOVS, ATOVS and SSM/I data
- Quality of the JRA-25 products relevant to satellite data

# Outlines of JRA-25

- Japan Meteorological Agency (JMA) and the Central Research Institute of Electric Power Industry (CRIEPI) are conducting Japanese 25-year Reanalysis.
- The reanalysis period of JRA-25 is 26 years from 1979 to 2004.
- Most of the observational data were supplied by ECMWF as used in their ERA-40 project. (We appreciate it.)
- Some new historical observational data are used:
  - Wind profile retrievals surrounding tropical cyclones supplied by Dr. M. Fiorino (PCMDI/LLNL).
  - AMV wind data with a quality indicator reprocessed by MSC/JMA.
  - Chinese daily snow depth data digitised from “Monthly Surface Meteorological Data in China” by MRI/JMA.

# Observation availability in JRA-25

Translucent : available but not used

White : not in JMA

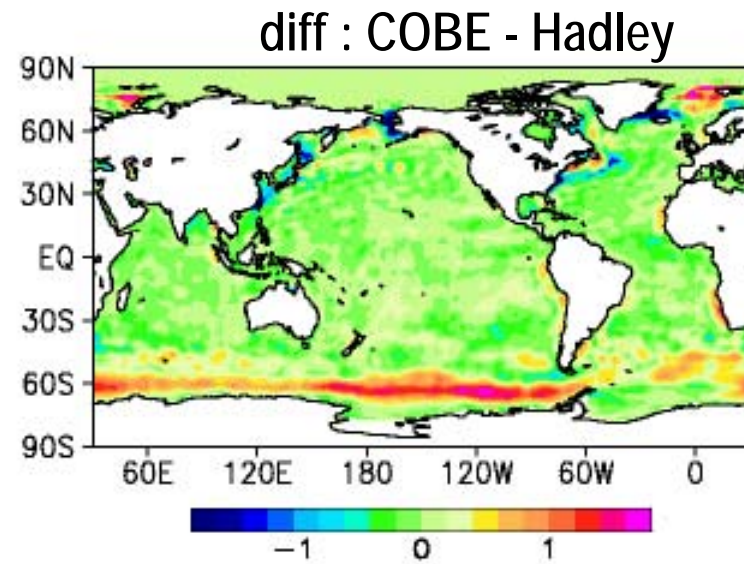

# Difference between JRA-25 and JMA operational GSM

|                           | <b>JRA-25</b>  | Operational (deterministic)  |

# The quality of the JRA-25 products

- Advantages

- Precipitation of JRA-25 has the highest correlation both with CMAP and with GPCP version 2 observational precipitation data sets among the reanalyses.
- The low-level clouds are in good consistency with the ISCCP observational cloud.
- Tropical cyclones are well captured both in the Western Pacific and in the Eastern North Pacific.
- Snow depth analysis is of good quality.

- Deficiencies

- There are some problems in hydrological cycle in the Amazonian area.
- There are some discontinuities in temperature time series for the stratosphere, which are coincident with satellite switching.

# Access to the JRA-25 products

- Basic products are available via the Internet.
  - <http://www.jreap.org/download/download-e.html>
  - Surface analysis, pressure level analysis, 2-dimensional physical monitor ....
  - 2.5 x 2.5 grid.
  - For research use only. Feedbacks from research are expected.
- Time series monitors for observational data and inter-comparison of reanalyses are also available.
  - [http://cpd1.kishou.go.jp/monitor/STA6/NpxMon\\_e.shtml](http://cpd1.kishou.go.jp/monitor/STA6/NpxMon_e.shtml)
  - [http://cpd1.kishou.go.jp/monitor/STA6/NpxMon\\_e.shtml](http://cpd1.kishou.go.jp/monitor/STA6/NpxMon_e.shtml)
- JRA-25 will be transitioned to the JMA Climate Data Analysis System (JCDAS) after 2005.

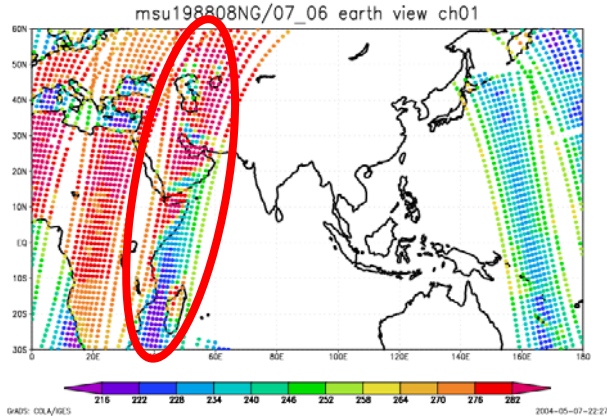

# Precise quality monitoring for TOVS data

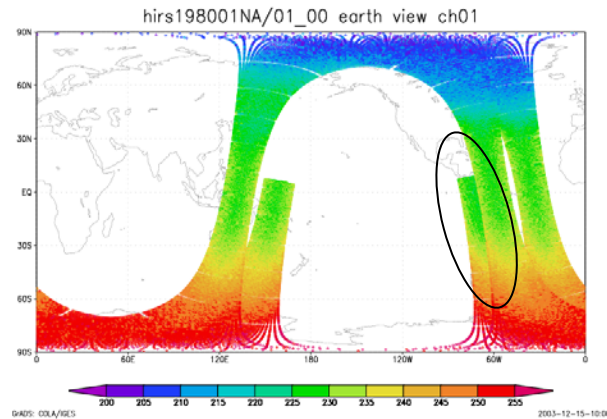

- The assimilation of poor quality data has a negative impact on the analysis. In order to prevent poor quality data being used, it is necessary to specify the channels, the instruments, the satellites and the periods, of poor quality.
- Fortunately, information about the quality of the TOVS data can be obtained from some sources (e.g. Kidwell, 1998; Hernandez et al., 2004).
- However, close examination into the TOVS data revealed that there are many poor quality data, which were not recorded in the sources.
- So, precise quality monitoring for the TOVS data was performed in advance to the JRA-25 production.

# Classification of poor quality data

Bad earth-location (a)  
Shift along the satellite track

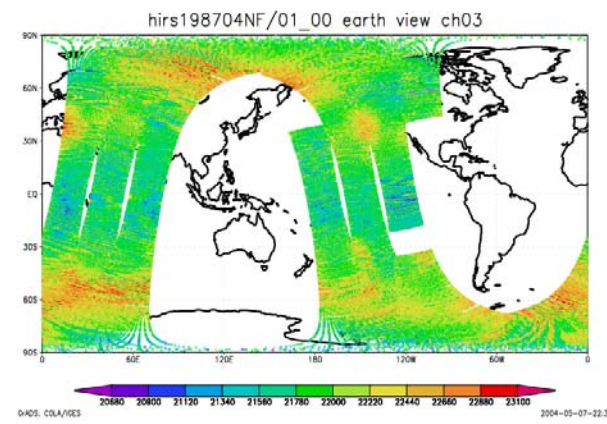

Bad earth-location (b)  
Incorrect time information

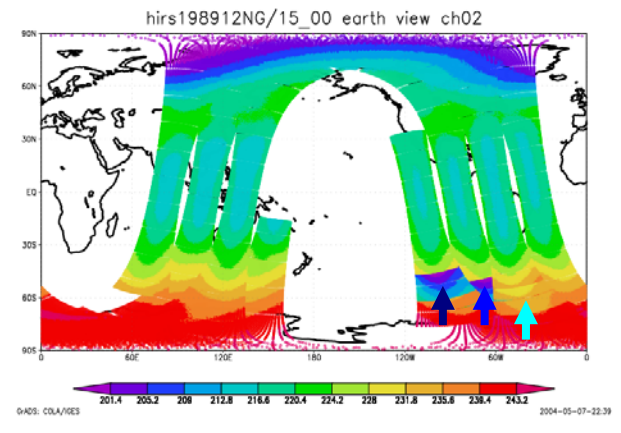

Bad earth-location (c)  
Scattered out

Periodic noise

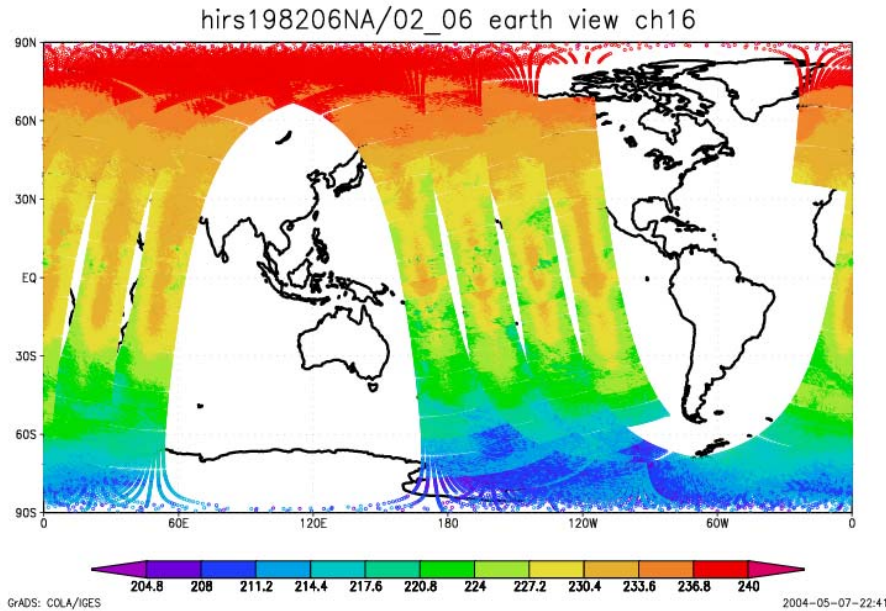

Random noise

Calibration error

# Classification of poor quality data

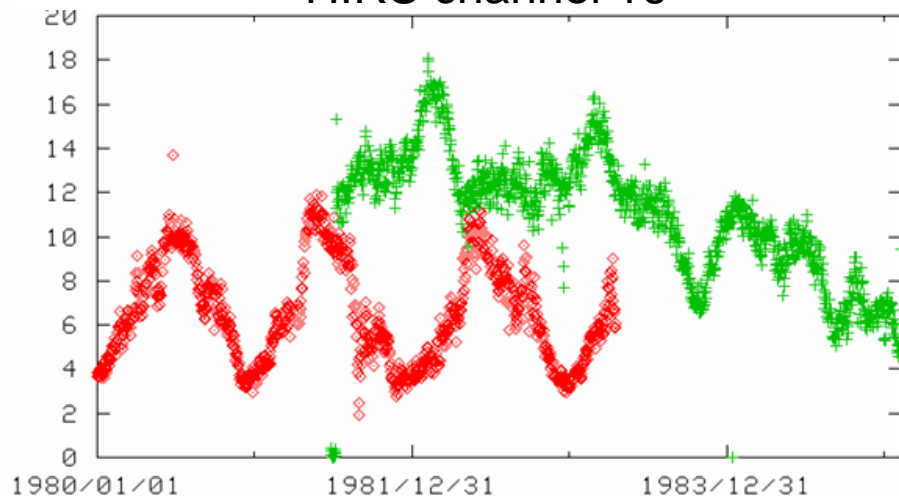

## Discontinuities of BT at the boundaries of a super swath of HIRS

This phenomenon is significant in CO<sub>2</sub> 4.3-micron channels (13-17).

The variation of PM satellites is larger than that of AM satellites, and gradually decreases with long-time drift in the local time of measurements.

HIRS channel 16

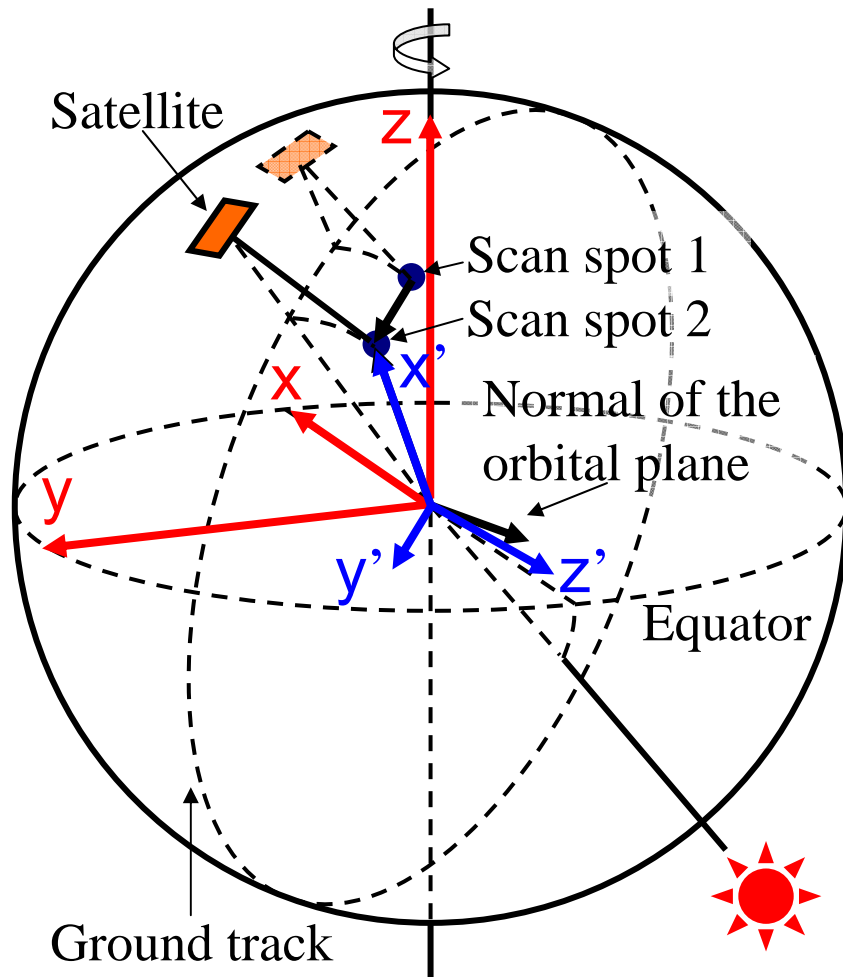

Red line: NOAA 6 Green line: NOAA

The ratio of the BT variation at the boundaries of a super swath to that of interior

$$ratio \equiv \frac{Quartile(\mu(1) - \mu(40))}{Quartile(\mu(i+1) - \mu(i))}$$

$i$ : scanline number  
 $\mu(i)$ : scanline mean of brightness temperatures

# Estimation of orbital elements

$$\begin{pmatrix} n_x \\ n_y \\ n_z \end{pmatrix} = \begin{pmatrix} k_x & l_x & m_x \\ k_y & l_y & m_y \\ k_z & l_z & m_z \end{pmatrix} \begin{pmatrix} n_{x'} \\ n_{y'} \\ n_{z'} \end{pmatrix}$$

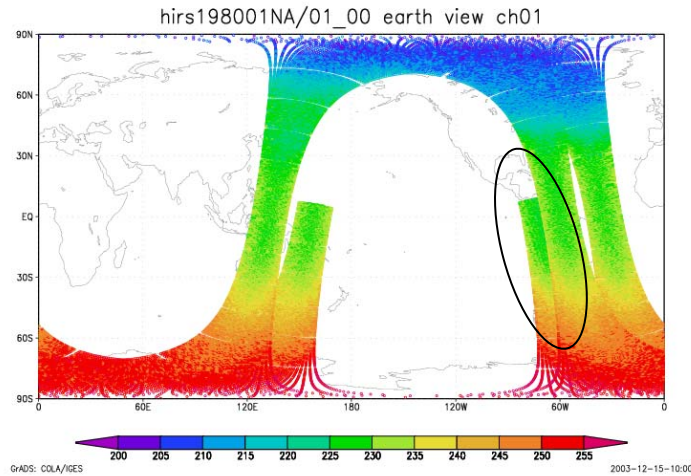

$(n_x, n_y, n_z), (n_{x'}, n_{y'}, n_{z'})$  :  
Normal of the orbital plane  
in  $(x, y, z)$  and  $(x', y', z')$

$(k_x, k_y, k_z), (l_x, l_y, l_z), (m_x, m_y, m_z)$  :  
Direction cosines of  $x'$ -,  $y'$ - and  $z'$ -  
axes in terms of  $(x, y, z)$

# Summary for precise quality monitoring for TOVS data

- Orbital elements of NOAA satellites can be estimated from earth-location of TOVS data with reasonable accuracy, and they are effective in monitoring bad earth-location.
- Calibration data are effective in quality monitoring, but available for the HIRS of TOVS only.
- It is desirable that further examination for level-1b data is performed, because:
  - Level-1b data include all the information required for calibration.
  - Comparison with the latest calibration algorithm would provide information about radiometric biases.

# Assimilating scheme for TOVS data

- RTTOV-6 is used for radiative transfer calculation.
- 1DVAR is performed as part of QC processes.
- In order to process HIRS and MSU data together in the 1DVAR, level-1d data were produced from level-1c data.
- **An adoptive bias correction scheme is used.**
  - Reference values are optimum solution of the 1DVAR.
  - No predictors. The coefficients are calculated for each 5K of observed BT.
  - The coefficients are calculated from the latest 4-day sample and revised every cycle.

| Sensor | CH No. | Peak of weighting function | Absorption gas                    |

The channels in yellow shade are used only in clear-sky, over sea spots.

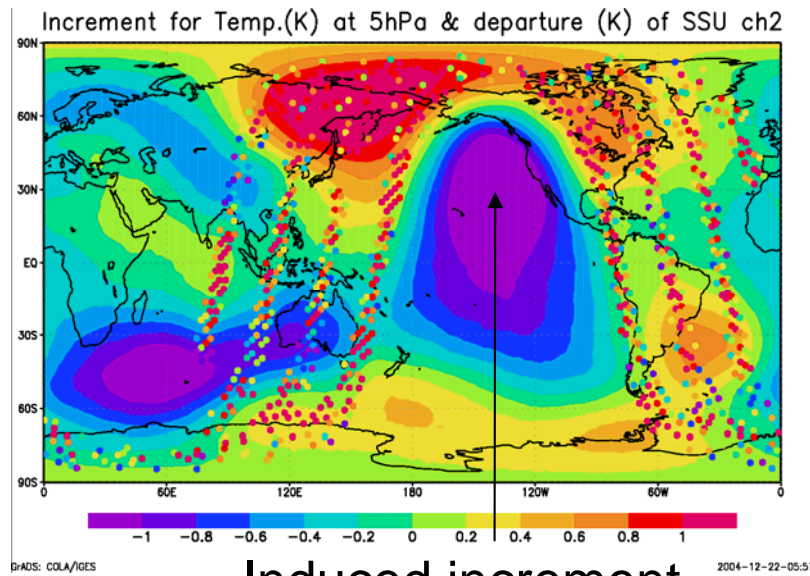

# Problem with bias correction of TOVS data

This bias correction scheme is intended to correct inconsistency among channels.

Difference between observations and background is not taken into account.

Consequently, large-scale analysis increments occurred in stratospheric temperatures in a preliminary experiment.

Induced increment  
18UTC JUL. 15 1991 with NOAA-11

# Extended time window for stratospheric observing channels

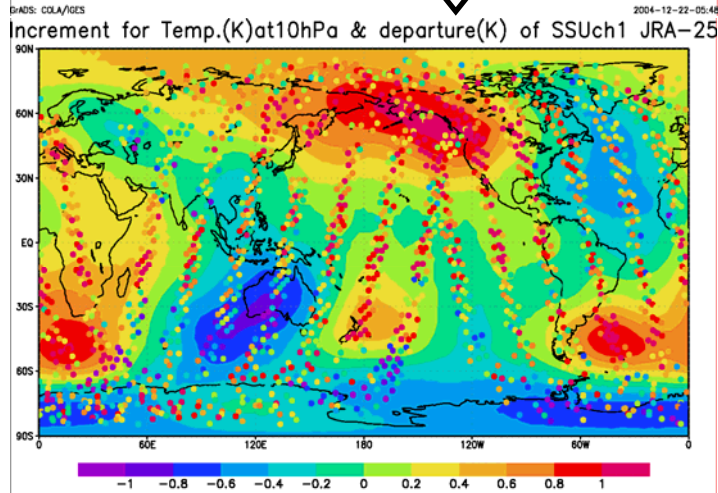

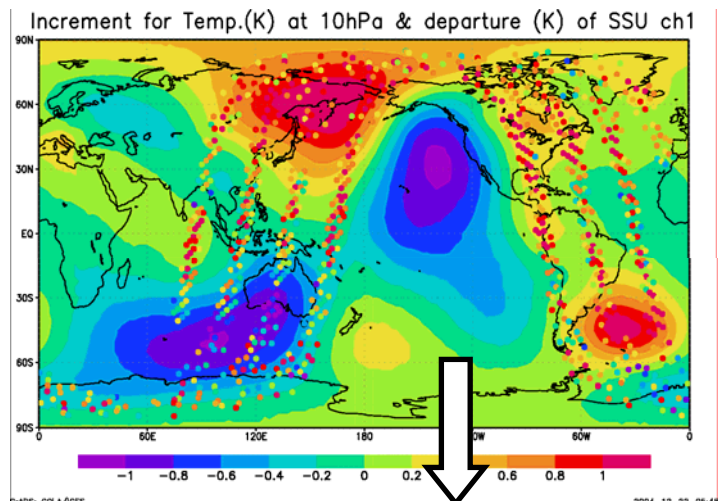

## Solution

We extend time window up to 12 hours for stratospheric observing channels, and thin strongly outside the original 6 hour time window.

# Extended time window for stratospheric observing channels

Extended time window prevents large scale induced increment.

18UTC JUL. 15 1991 with NOAA-11

# Assimilating scheme for ATOVS data

- RTTOV-7 is used for radiative transfer calculation.
- A static bias correction scheme is used.
  - Scan-bias correction
    - Both for AMSU-A and for AMSU-B
  - Air-mass bias correction
    - For AMSU-A only
    - Reference data are radiosonde observations.

$$BC = a_0 + a_{surf} \times T_{surf} + \sum_{ch}^{5,7,10} a(ch) \times T_{BB}^{cal}(ch)$$

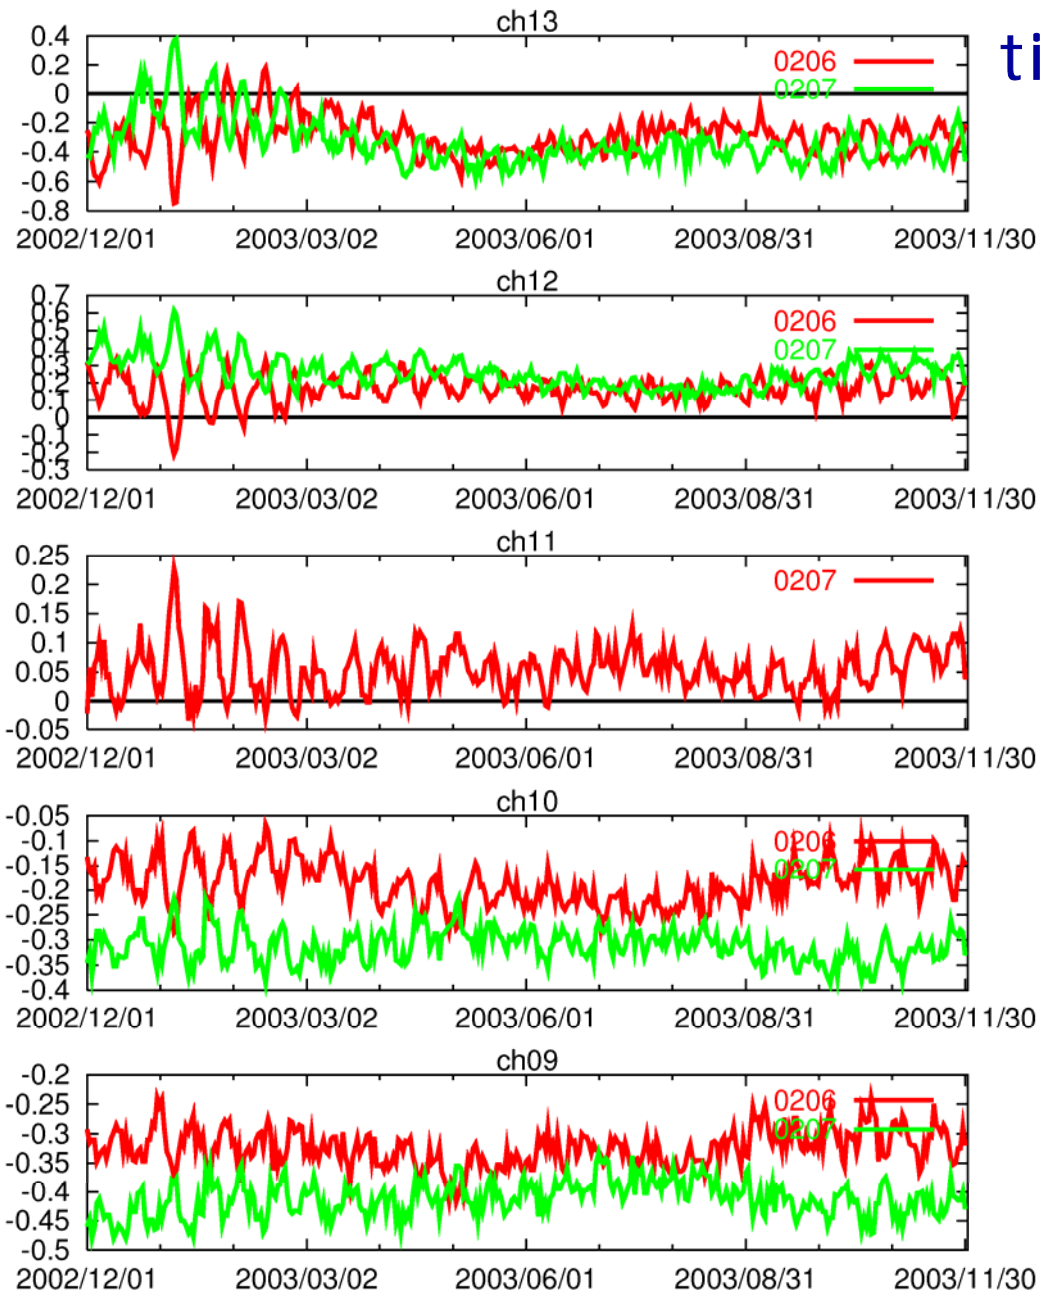

| Sensor | CH No. | Center frequency (GHz)            | Absorption gas   |

Dec. 1991  
(with SSM/I)

Blue colors indicate moistening by the assimilation.

# Global mean monthly precipitation

# Temperature time series for the stratosphere

In JRA-25, big jumps occurred early in 1995 and in October 1999.

The former is coincident with the period for which observations from the SSU were absent.

The latter is coincident with the time at which the ATOVS replaced the TOVS.

# Stratospheric Sounding Unit (SSU)

Assuming that absorption lines are strong, isolated and Lorentz shaped, an analytical expression for the peak pressure of the weighting function would be expected as follows (Taylor et al. 1972, *Appl. Opt.*):

$$P_{peak} = \left[ \frac{4(1+b)l}{a} \right]^{\frac{1}{2}} P_0$$

$P_0$ : the mean pressure of the CO<sub>2</sub> cell

$a$ : the total amount of CO<sub>2</sub> in the atmosphere (atm cm/atm)

$b$ : the self-broadening coefficient for CO<sub>2</sub>

$l$ : the length of the CO<sub>2</sub> cell.

The optical system and pressure modulator of SSU

quoted from Miller et al., 1980, *Phil. Trans. R. Soc. Lond.*

It depends on  $P_0$  and  $a$ , but they are assumed to be constant in JRA-25.

# Summary for the quality of the JRA-25 products relevant to satellite data

- Precipitation of JRA-25 has the highest correlation with CMAP among the reanalyses.
  - The bias correction for SSM/I data was performed to adjust to background TPW.
  - Strict QC was performed for water vapor channels of HIRS.
- There are some discontinuities in temperature time series for the stratosphere, which are coincident with satellite switching.
  - Inappropriate bias correction for the stratospheric observing channels of TOVS and ATOVS.
  - The bias is partly because of inappropriate spectroscopic parameters assumed in the radiative transfer calculation.
