

Main WP4 tasks

- **T4.1 - Quality control, bias adjustment and homogenisation of input observations**
- UNIVIE, ECMWF, UBERN, FFCUL
- Assess and improve the quality of input observations used for reanalysis. This includes quality control, bias adjustment and homogenization of observations.
- **T4.2 - Diagnostics and uncertainty assessments of reanalysis output**
- UNIVIE, ECMWF, RIHMI, DWD, UVSQ
- Quality assessment of reanalysis products. Deliverables consist of Reanalysis Quality Assessment reports.
- Integration and expansion of diagnostic tools for estimating the uncertainty of new assimilation products. Assessment of the **"climate quality"** of the reanalysis products.

Main WP4 tasks

- ECMWF, ocean, carbon communities already have excellent monitoring tools - so where can we contribute?
 - Ensure that essential metadata are right - this is assumed in ECMWF QC
 - Assess and adjust observation biases
 - Check fulfilment of budget constraints
 - Physical relationships as seen in different data sets
 - Help with intercomparisons of (reanalysis) data sets
- Do existing diagnostics meet users' need?

Time varying biases as seen in background departures and budget evaluations

Leopold Haimberger, Marco Milan, Michael Mayer,
Michael Blaschek, Lorenzo Ramella-Pralungo,

ERA-CLIM2 General Assembly, Nov 20th, 2014

Diagnostic tools

Diagnostic	State X	Observations y	Predicted fluxes F_x	Observed fluxes F_y
Background departures	$Y-H(X)$	$Y-H(X)$	$F_{y-H}[F_x(X)]$	$F_{y-H}[F_x(X)]$
Comparison of (input) obs.		$Y_a-H(y_b)$		$F_{y_c-H}[F_{y_d}]$
State perturb.	$AnInc(X)$		Spinup(F_x)	
Tend+Fluxdiv+ Conversion=0?	$X_{fc}, F_x(X_{fc})$ $X_{an}, F_x(X_{an})$	Tend(y), Fluxdiv(y)	$F_x(X_{fc})$	F_y
Diagnostic relationships	X_c vs. X_d	y_c vs. y_d	$F_{x_a}(X_{fc})$ vs. $F_{x_a}(X_{fc})$	F_{y_c} vs F_{y_d}
Forecast skill	$fs[Y, H(X_{fc})]$, $fs(X_{fc}, X_{an})$			$fs(F_y, H[F(X_{fc})])$
OS(S)Es	$X(y)$ vs $X(y_b)$			$X(F_y)$ vs $X(F_{y_b})$

... other, more specialized diagnostics for data assimilation

Departure time series of early radiosonde data

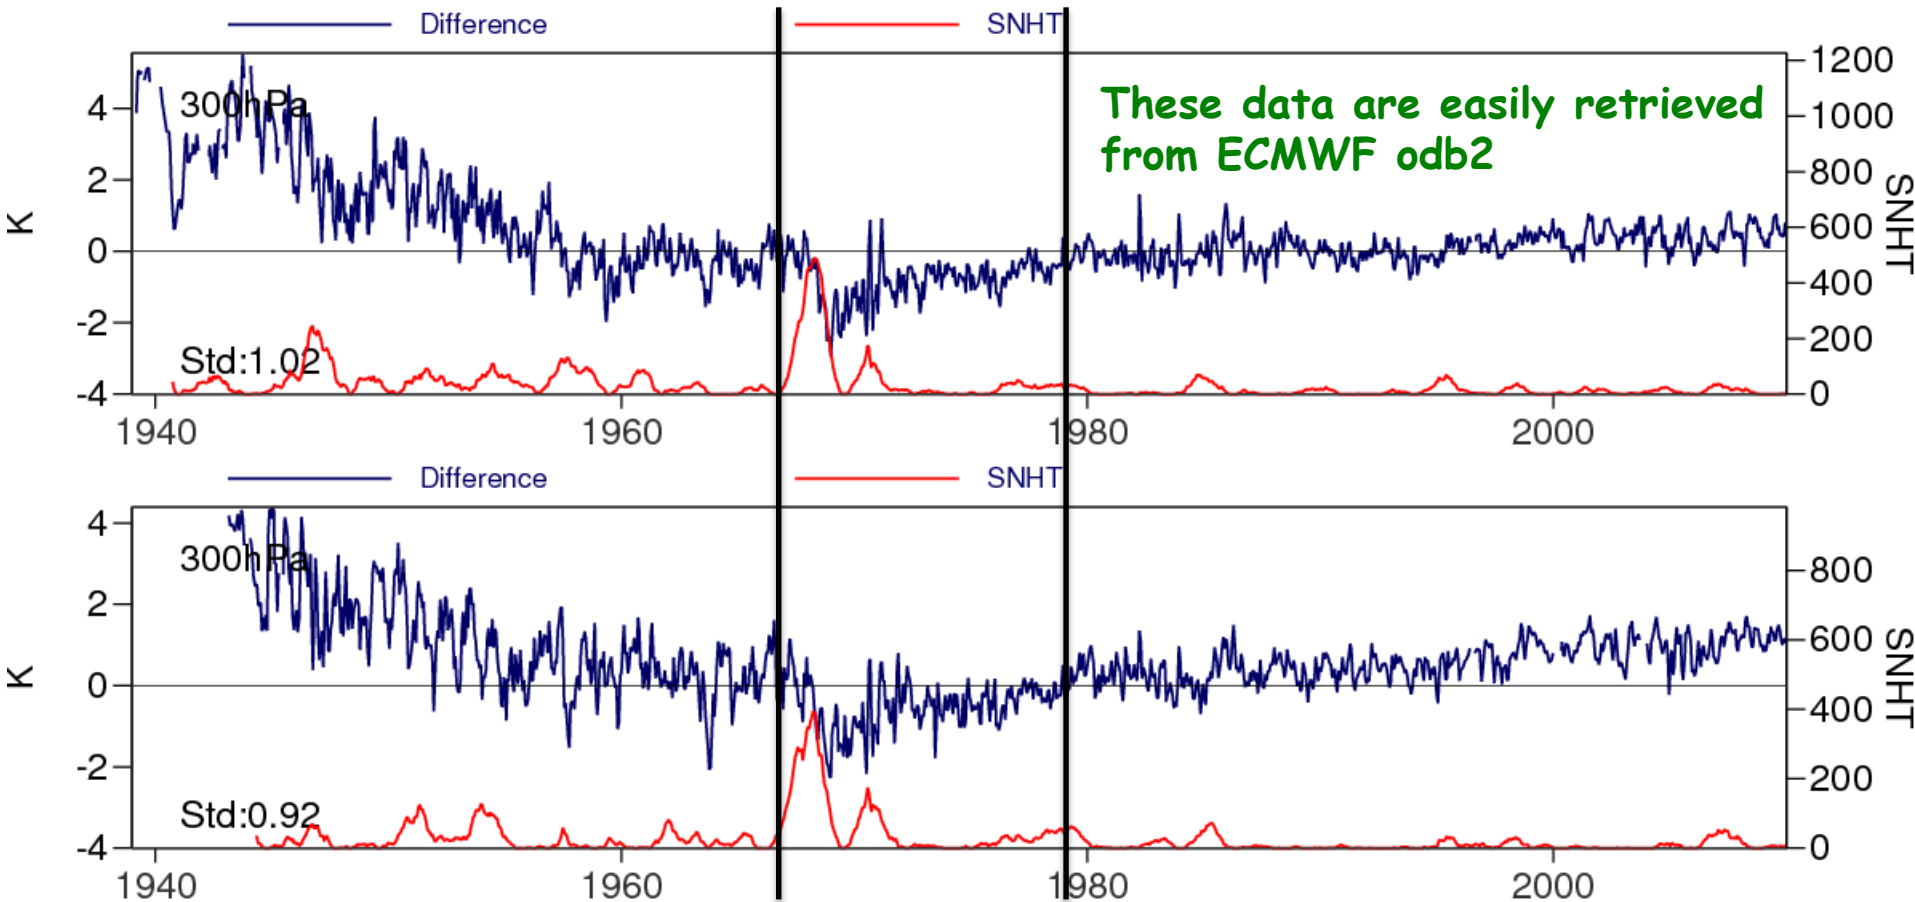

- Background ($y-Hx_b$) and analysis ($y-Hx_b$) departure statistics from pilot assimilations and reanalyses
- These series can be considered third level of QC after basic QC, internal consistency QC
- **Credo: Departure statistics have high potential for QC/BC**
- **ERA-PreSAT background departures 1939-1967**
- **ERA-40/ERA-Interim background 1968-1978, 1979-2013**
- **Use also analysis departure statistics from**
 - ERA-20C ensemble member 0 (rerun)
 - 20th Century Reanalyses v2 ensemble mean

ERA-20C

NOAA-20CR

US composite

Background departures,072202-072913, 00h

Background departures,072202-072913, 00h

T-Trends, 300hPa, 1949-1967

Unadjusted temperature

ERA-PreSAT bg

These data are easily retrieved from ECMWF odb2
Very strong cooling in obs over most of FSU, less so in bg
Good agreement over Europe, US

T-Trends, 300hPa, 1949-1967

ERA-20C analysis

NOAA-20CR analysis

No sign of cooling over FSU at all in surface data only reanalyses!

RAOBCORE adjusted temperatures

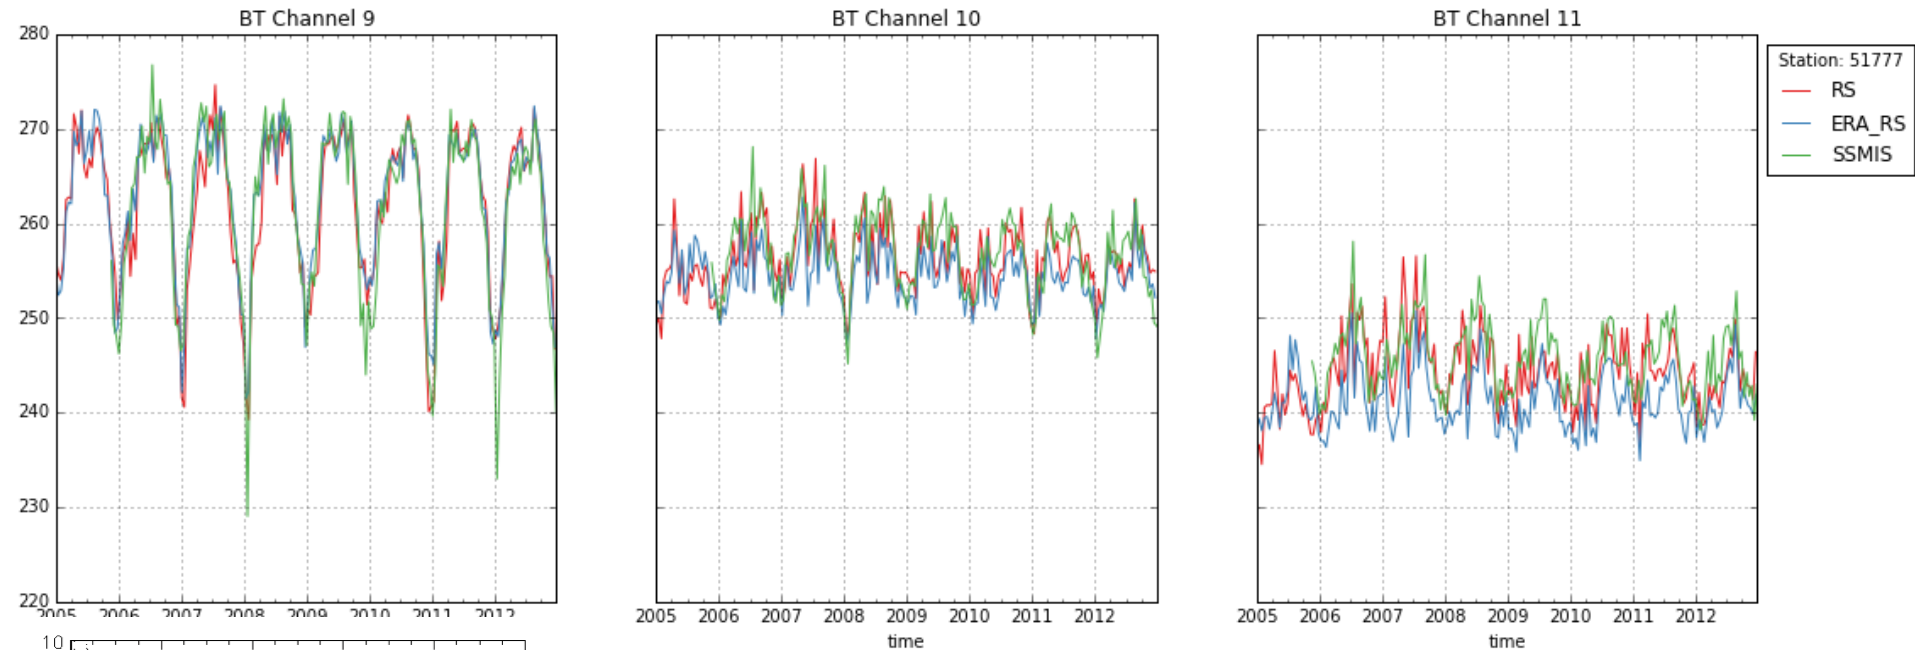

Method does not detect trend-like bias changes
ERA-presat bg also has cooling;
Departures from surface data only reanalyses have large variance

Status of offline homogenization

- RAOBCORE/RICH adjustments available back to 1958
- RAOBCORE/RICH adjustments back to 1939
 - RAOBCORE results there depend on reference used, much better break detection with ERA-presat
 - RICH needs to avoid neighbours from same country more strictly
- Wind data adjustments: available back to 1920s, Ramella-Pralungo et al. 2014a,b,c
- Humidity: just started
 - Calculate SSM radiances from RS profiles (using RTTOVs)
 - Analyse Humidity background departures

SSM-T2 brightness temperatures at single station

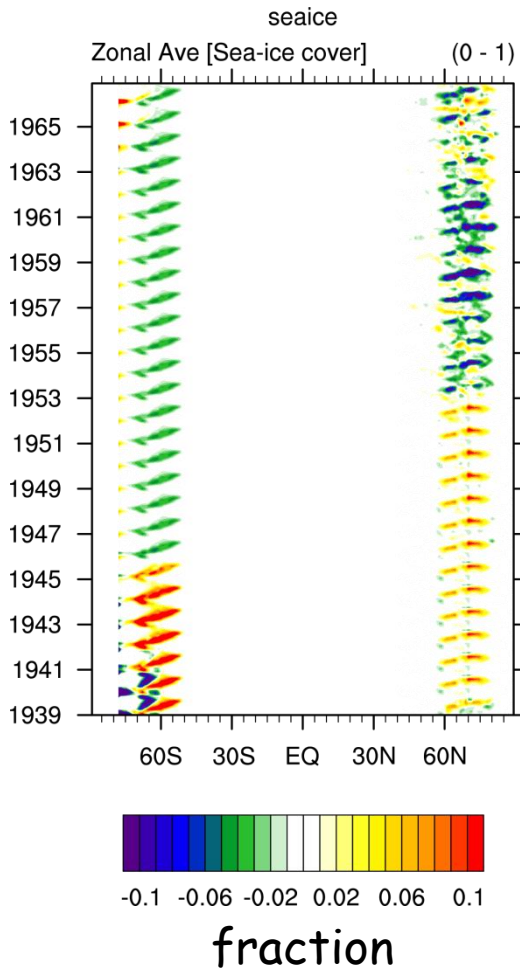

- RTTOVS 10 used for calculating BTs
- Potential for intercomparison back to early 1990s
- Comparison with GPS-RO?
- Background departures will be examined and interpreted with healthy scepticism

Flux diagnostics

- Relationships between fluxes, state variables
- Mean Analysis increments indicate flux imbalances in early forecast steps
- Variability of fluxes as interesting as variability of state
- Fluxes should fulfil budget constraints, e.g. for vertically integrated total energy

ERA-Interim

TETEND ANA-FC 3-month-ave

Surface flux and sea ice extent

- Robust relationship between summer surface energy flux and September ice extent anomalies
- Indirect F_S estimate from satellite data and atmospheric budgets yields even clearer results

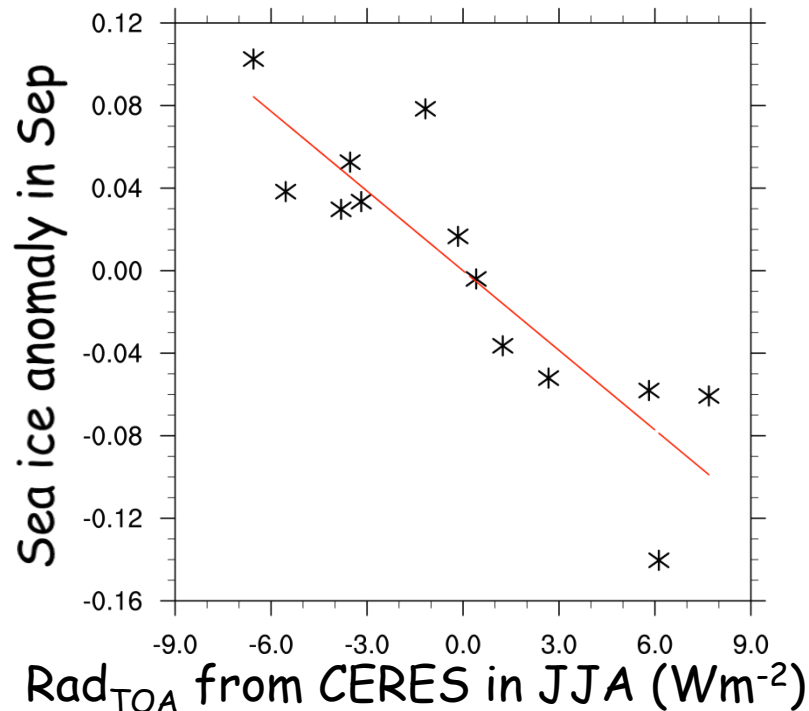

Radiation at TOA and sea ice extent

- Summer (JJA) Rad_{TOA} clearly has strong impact on September sea ice extent
- Reanalysis has difficulties to show this, probably due to cloud biases

Area averages 70N-90N

Area averages 70N-90N

Do these results improve anything ?

- (Radiosonde) observation bias estimation
 - Offline:
 - Ready for wind (Ramella-Pralungo et al. 2014),
 - backward extension for Temperature to pre-1958 ongoing
 - Online: Bias model for VarBC of Radiosonde-T ->Marco Milan
 - Implemented by end of year but not sufficiently tested
- Budget diagnostics:
 - Need to be communicated early to have a chance of improvement within project
 - Valuable tool to discover physical relationships
- Need „canonical“ set of diagnostics for comprehensive intercomparison of reanalysis, flux data

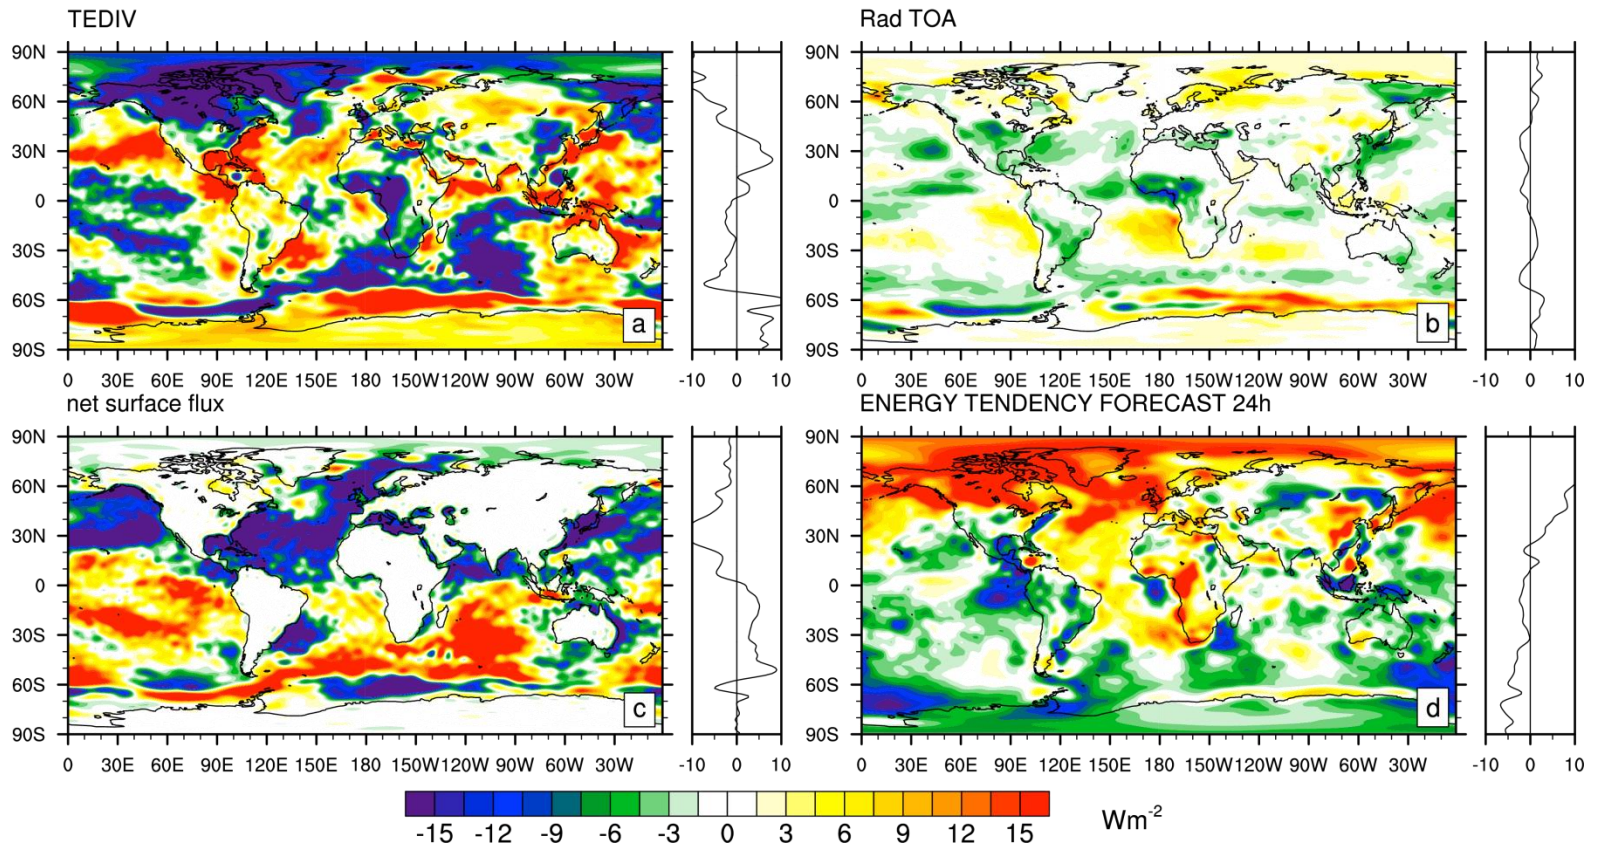

ERA-CLIM2 General Assembly 20 Nov 2014

Conclusions

- Radiosonde T/wind bias estimation offline/online:
 - Deliverable due at end of year
 - Implemented but testing delayed
- Budget diagnostics:
 - Reveal problems but not necessarily a solution. Communication with „modelers“ important
 - Emphasis on polar regions planned
- So far most work in WP4 in parallel, without much interaction except with ECMWF.
